14. ABSTRACT

Bone metastases are a debilitating and devastating complication for patients with advanced prostate cancer. Unfortunately, treatment options for patients with bone metastases are limited. Both hyaluronan synthase (HAS) and hyaluronic acid (HA) are upregulated in metastatic prostate cancer cells. 7-Hydroxy-4-Methyl Coumarin (HMC) is an inhibitor of hyaluronan synthase, commonly available in herbal supplements and, up to now, used mainly for digestion complaints. We proposed that it may be efficacious in the prevention and treatment of prostate cancer. Our hypothesis is that hyaluronic acid (HA) is utilized by prostate cancer cells to facilitate metastasis. Thus, reducing the production of HA should reduce the metastatic potential of prostate cancer cells making HA an ideal target for preventing and treating metastatic disease. The goal of this current research proposal is to determine whether reduction of HAS, via treatment with HMC, will prevent prostate cancer metastasis to bone and other organs or serve as a viable treatment for established bone metastasis. We have shown that HA protein levels in vitro correlate with metastatic potential and HA levels can be modulated in vitro using HMC. Furthermore, we have shown the in vitro growth of prostate cancer cells is slowed by inhibition of HA with HMC. In addition, we now have demonstrated that HMC can slow in vivo prostate cancer growth. We have observed modest effects of HMC on bone metastases. HMC appears have mild effects on preventing bone metastases. However, HMC had no effect on established bone metastases.

INTRODUCTION

Bone metastases are a debilitating and devastating complication for patients with advanced prostate cancer. Unfortunately, treatment options for patients with bone metastases are limited. Both hyaluronan synthase (HAS) and hyaluronic acid (HA) are upregulated in metastatic prostate cancer cells. 7-Hydroxy-4-Methyl Coumarin (HMC) is an inhibitor of hyaluronan synthase. It is commonly available in herbal supplements and, up to now, has been utilized mainly for digestion complaints. We proposed that it may be efficacious in the prevention and treatment of prostate cancer. Our hypothesis was that hyaluronic acid (HA) is utilized by prostate cancer cells to facilitate metastasis. Thus, reducing the production of HA should reduce the metastatic potential of prostate cancer cells making HA an ideal target for preventing and treating metastatic disease. The goal of this research proposal was to determine whether reduction of HAS, via treatment with HMC, would prevent prostate cancer metastasis to bone and other organs or serve as a viable treatment for established prostate cancer bone metastasis. Our in vivo evidence demonstrates that HA protein levels in vitro correlate with metastatic potential in vivo and that HA levels can be modulated in vitro using HMC. Furthermore, we have shown the in vitro growth of prostate cancer cells is slowed by inhibition of HA with HMC. We also now have evidence that HMC has some effects on in vivo tumor growth. However, the drug in its current formulation, while not as hard on the animals as the acidic form of HMC, still does not appear to be well tolerated by the animals. This is less of an issue when HMC is used in a preventative method to prevent bone metastases. However, when used to treat existing bone metastases, we saw very little effect. We believe this is because the mice were already too sick to tolerate HMC and its side effects. A long term future goal of this work is to try to develop a formulation of HMC that would allow us to target it to the site of the tumor (either in bone or other tissues) rather than treat systemically, thus, reducing the side effects.

BODY

TASK 1: Determine whether hyaluronan synthase (HAS) expression and hyaluronic acid (HA) production in prostate cancer cells correlates with increased growth both in vitro and in vivo and whether modulation of HAS expression by 7-Hydroxy-4-Methyl Coumarin (HMC) will inhibit tumor growth in the primary (subcutaneous) site. (Months 1-12)

RESEARCH ACCOMPLISHMENTS:

a. Levels of HAS2 and HAS3 expression in established prostate cancer cell lines, PC-3, LN.CAP-LN3, VCaP, DuCaP, DU-145 and 22RV1 was determined by quantitative expression analysis and compared to expression levels in non-tumor prostate epithelial cell lines, PZ-HPV-7 and RWPE-1. HAS2 and HAS3 levels were determined in each of the cells lines listed above by quantitative expression analysis. Results are shown in Figures 1 and 2 below. HAS1 expression was undetectable in the cancer cell lines.
Figure 1. **Quantitative Analysis of HAS2 Expression levels by Real-Time PCR.** HAS2 expression is reported relative to expression in the RWPE-1 prostate epithelial cell line. Note that all of the prostate cancer cell lines except for LNCaP-LN3 express HAS2 at higher levels than prostate epithelial cell lines, RWPE-1 and PZ-HPV-7. DuCaP+ indicates DuCaP cells harvested with a feeder layer. DuCaP indicates only the isolated DuCaP cells.

Figure 2. **Quantitative Analysis if HAS3 Expression levels by Real-Time PCR.** HAS3 expression is reported relative to expression in the RWPE-1 prostate epithelial cell line. Note that not all of the prostate cancer cell lines express HAS3. DuCaP+ indicates DuCaP cells harvested with a feeder layer. DuCaP indicates only the isolated DuCaP cells.

PC-3, the most aggressive of the prostate cancer cell lines, in vivo, expressed both HAS2 and HAS3 at much higher levels than the prostate epithelial cell lines, RWPE-1 and PZ-HPV-7 and the other prostate cancer cell lines. These differences are not nearly as
remarkable as those observed with HAS2 expression. This indicates that HAS2 likely plays a much more important role in HA production in this cell lines. Interestingly, these results do not correlate with our initial studies which indicated increased HAS3 expression in DU-145 and VCaP cell lines as well. This data have now been reproduced for verification and inclusion of LN.CaP-LN3 data, which had not previously been analyzed for expression.

b. HA synthesis was quantitated in the same cell lines examined in sub-task 1a using a competitive binding assay specific for HA. Again, non-tumor prostate epithelial cell lines, PZ-HPV-7 and RWPE-1 were utilized as controls (Figure 3). These results correlate with in vivo tumorigenicity and metastatic potential which has been previously determined in our laboratory.

![Graph showing HA synthesis by prostate cancer cell lines.](image)

**Figure 3. HA synthesis by prostate cancer cell lines.** Note that the metastatic prostate cancer cell lines, PC-3, VCaP and DU-145 make HA. PC-3 cells make significantly more HA than other prostatic cancer cell lines and the prostate epithelial cell lines, PZ-HPV-7 and PWRE1. The other prostate cancer cell lines make very low levels or undetectable levels of HA. These results correlate with in vivo tumorigenicity and metastatic potential.

c. The prostate cancer cell lines were treated in vitro with HMC, a known inhibitor of HAS. Conditioned media was collected after 48 hours of incubation and quantitative expression analysis of HAS2 and HAS3 (Figures 4 and 5), HA synthesis (Figure 6) and in vitro growth rate (Figures 7-13) were examined in both HMC- and vehicle-treated cells. Cytotoxicity assays were performed using commercial colorimetric cell proliferation assays (Promega), based on the cleavage of tetrazolium salts by mitochondrial dehydrogenases (MTS) in viable cells, but were uninformative due to interference of HA with the assay.
Figure 4. Quantitative Analysis of HAS2 Expression levels by Real-Time PCR. HAS2 expression is reported relative to expression in the vehicle treated RWPE-1 prostate epithelial cell line. HMC treatment reduced HAS2 expression levels in all of the cell lines except DU145. We have repeated this experiment to obtain data with DuCaP and LN.CaP-LN3 cells lines which were not available when this experiment was first performed and to verify the other data.

Figure 5. Quantitative Analysis of HAS3 Expression levels by Real-Time PCR. HAS3 expression is reported relative to expression in the vehicle-treated RWPE-1 prostate epithelial cell line. HMC treatment reduced HAS3 expression levels in all of the cell lines except DU145 and the prostate epithelial cell line PZ-HPV-7. We are currently investigating the reasoning for this. We
have now repeated this experiment to obtain data with DuCaP and LN.CaP-LN3 cells lines which were not available when this experiment was first performed. Note that DuCaP cells do not express HAS3.

Figure 6. HA synthesis by prostate cancer cell lines. Note that the metastatic prostate cancer cell lines, PC-3, VCaP and DU145 make HA and thus were included in this experiment. HA production was significantly reduced in both PC-3 and VCaP but not in DU145 cells, consistent with the results of HAS2 and HAS3 expression analysis (Figures 4 and 5). The other prostate cancer cell lines make very low levels or undetectable levels of HA by this assay and thus were not included here.

These results are very interesting particularly since it appears that HA levels and HAS expression in DU145 may not be affected by inhibition of HAS by HMC. This warrants further investigation and will be explored outside the confines of this grant.
Figure 7 (a-h). In vitro growth of vehicle-treated and HMC-treated prostate cancer cell lines. Growth curves were generated by plating 1X10^4 cells in media supplemented with either HMC or vehicle and counting at 4h, 24h, 48h, and 72h. The growth of all cell lines including nontransformed prostate epithelial cell lines, RWPE-1 and PZ-HPV-7, was significantly reduced by treatment with HMC.

d. To determine the safest dose of HMC in athymic nude mice, animals were divided into three groups and each group treated daily with a different concentration (100 mg/kg, 250 mg/kg and 500 mg/kg respectively) of HMC. This was to allow us to identify the highest dose that is well-tolerated by the animals.

These experiments were performed using an acidic form of HMC. The mice tolerated this form reasonably well even at the highest dose proposed, even though the solution was thick.
and chalky. However, little if any change was seen in HA levels. After some discussion with Dr. Leach, the co-investigator on this grant, regarding the bioavailability of HMC, we scaled up on the doses of HMC and tested it at 3 higher concentrations (1.5g/kg, 2.5g/kg and 3.0g/kg). The bioavailability of HMC is very low and thus, an increase in dosage should increase the actual bioavailable HMC. Because the acidic form of HMC was difficult to get into solution, particularly so at higher concentrations, it was decided very recently to try to use the salt form of HMC. We have tested this form in mice at the dose of 1g/kg/mouse/day, which has been used previously in other studies. This dose was well tolerated by the animals as were the lower doses. Thus, we proceeded with the remainder of the experiments using this form once we verified that there is a change in HA levels in our test mice. The data on HAS2 and HAS3 expression and HA production has already been confirmed using the salt solution of HMC. The remainder of the in vitro data has also been repeated to verify that this form will be as effective as the acidic form on the growth of prostate tumor cells. To illustrate how similar the two compounds behave in vitro, we performed a side by side comparison in vitro (see Figure 8 for example).

![Growth Curve](image)

**Figure 8. Growth curve of PC-3 cells comparing HMC-salt solution with the acidic form of HMC.** Note that there is no difference between the two compounds.

e. To determine the effects of HMC on the growth of prostate cancer cells in vivo, nude mice were inoculated with each of the prostate cancer tumor cell lines (n=16 mice per cell line; 8 per treatment group) and treated with the 1mg/kg/day dose of the HMC salt solution or with vehicle. (8 mice per group X 6 cell lines X 2 groups = 96 mice total X 2 experiments**). This has been modified to five cell lines. Prostate cancer cell lines, PC-3, DU-145, VCaP, LNCaP, LN3 have been examined thus far. DuCaP cells are no longer being used as they will not consistently form tumors in nude mice. 22RV1 cells were also eliminated because of a lack of consistent tumor formation in mice.
Figure 9: HMC effects on tumor volumes and tumor wet weight at sacrifice.  
a) In vivo growth curve of PC-3 tumors treated with control or HMC. Note HMC slowed the growth of the tumors.  
b) In vivo growth curve of VCaP tumors treated with control or HMC. Again, note that HMC slowed the growth of the tumors.  
c) PC-3 tumor weight at sacrifice following in vivo treatment with control or HMC. Note that HMC significantly reduced the tumor weight (p=0.021).  
d) VCaP tumor wet weight at sacrifice following in vivo treatment with control or HMC. Note that HMC also significantly reduced the tumor weight (p=0.0204).  
e) In vivo growth curve of DU-145 tumors treated with...
control of HMC. Note that HMC increased tumor growth and tumor wet weight (f) at sacrifice in DU-145 tumors. This is consistent with the in vitro data. There was no difference in the growth curve or final tumor wet weight with LN.CaP.LN3 cells (data not shown).

![Serum HA Levels](image.png)

**Figure 10. Serum HA levels at sacrifice in mice bearing tumors as indicated and treated with either HMC or control.** Note that both VCaP and PC-3 tumor bearing mice had a significant decrease in HA levels consistent with the significant decrease in tumor size.

**Outcome:** Expression of HAS and HA production has been established and shown to correlate with *in vivo* tumorigenicity and metastatic capability. Dosage of HMC for *in vivo* studies has been established and effect of the compound on tumor growth determined. HMC had significant effects on the growth of both VCaP and PC-3 cells in vivo. These two cell lines have been selected for further study on the effect of this compound on bone metastases.

**TASK 2: Determine whether inhibition of HAS expression and HA production with HMC will prevent metastases of prostate cancer cells to bone and other organs in mouse models of bone metastases.** Mice will be pre-treated with HMC to mimic the clinical scenario whereby a patient is diagnosed with advanced prostate cancer and may be at risk for bone metastases, but has no evidence yet of skeletal lesions at diagnosis. HMC could then be used to augment standard of care to prevent metastases. *(Months 13-24)*

a. Athymic nude mice were treated with the optimal dose of HMC or vehicle daily for two weeks prior to tumor cell inoculation (n=12 per group X 2 cell lines X 2 treatments X 2 experiments **for a total of plus 96 mice**)

b. Originally, we planned to treat PC-3 and VCaP prostate cancer cells with HMC or vehicle *in vitro* prior to inoculation into mice. However, because HMC has such significant effects on growth of these cells in vitro, we are not be pre-treating the cells.
Mice were inoculated with either PC-3 cells or VCaP cells via intra-cardiac inoculation. Mice were treated with the 1mg/kg/day dose of HMC or vehicle and treatment on a daily basis for the duration of the experiment.

a. Mice were examined by radiography at baseline and weekly post heart injection for the development of bone metastases in the case of PC-3, where skeletal lesions will develop more rapidly and most likely will be osteolytic in nature. VCaP cells cause a more osteoblastic phenotype and take longer for the development of bone metastases so these mice are being x-rayed once per month until there is evidence of bone metastases in control animals and then more frequently. This will allow us to track the development of skeletal metastases over the course of the experiment.

b. Serum samples were harvested at baseline and once per month until sacrifice so that we can measure HA levels over the course of the experiment, as well as markers of bone turnover as indicators of bone metastases.

c. We had planned to examine half of the mice in each group (n=6 per group X 2 cell lines X 2 treatments) by 18F-FDG MicroPET at sacrifice for the identification of metastases to other organs. However, due to circumstances beyond our control, the PET scans cannot be performed. The University’s microPET scanner is broken.

d. At sacrifice, tissues from each mouse were harvested for histological preparation. Quantitative bone histomorphometry was performed on sections of long bones to determine the effects of HA on bone metastases.

**Outcomes:** Experiments performed with the VCaP cell line proved to be inconclusive. In the prevention experiments, we did not see development of bone metastases in the experimental or control groups and no effect on survival was observed. Thus, after repeating these experiments and still failing to see any development of bone metastases, we focused our efforts on the PC-3 model.

As in our previous experiments with PC-3 cells in the subcutaneous site, we were able to detect a significant decrease in HA levels in serum. However, what we expected to be promising results initially, resulted in minimal effects of HA on bone metastases. There was only a slight reduction in the percent of mice with metastases to all sites (Figure 11). This is likely because HA had effects on primary tumor growth and invasion but not necessarily on bone metastatic tumors.
Figure 11. Percent of mice with metastases to all sites following preventative treatment with HMC or Vehicle. Note that HMC may preventative treatment may have caused a slight decrease in the number of animals with metastases but the difference is not statistically significant.

Interestingly, in the preventative setting, HMC had no effects on bone mineral density but when harvested bones were examined histologically, mice treated with HMC in a preventative manner had decreased trabecular bone volume at both the mid-femoral and mid-tibial metaphyses (Figure 12). Treatment with HMC in a preventative manner resulted in no change in survival compared to control treated mice. Thus, despite our initial hope, HMC does not appear to work in a preventative manner.

Figure 12. Trabecular bone volume/Total volume at mid-femoral and mid-tibial metaphyses. Note the statistically significant reduction in trabecular bone volume in mice treated with HMC compared to vehicle at the mid-femoral metaphysis. The difference between HMC treated and vehicle treated groups was not significant in the mid-tibial metaphyses, although a similar trend does appear to exist.
**TASK 3:** Determine whether inhibition of HAS via treatment with HMC will be beneficial in animals with established prostate cancer bone metastases utilizing the same model used in **Specific Aim 2.** In this case, mice were monitored radiographically for the development of bone metastases, and treatment with HMC will not begin until 75% of the mice have evidence of bone metastases. This would mimic the clinical scenario in which patients present with bone metastases at the time of diagnosis. *(Months 25-36)*

a. Athymic nude mice will then be inoculated with PC-3 cells via intra-cardiac inoculation.

b. Mice will be examined by radiography at baseline and then weekly beginning at 2 weeks post heart injection for the development of bone metastases in the case of PC-3, where skeletal lesions will most likely be osteolytic in nature and develop more rapidly.

c. Daily treatments with the optimal dose of HMC or vehicle began when 75% of the mice had evidence of bone metastases by radiography.

d. Serum samples will be collected at baseline and once per month until sacrifice so that we can measure HA levels over the course of the experiment as well as markers of bone turnover as indicators of bone metastases.

e. We originally planned to examine half of the mice in each group by $^{18}$FDG MicroPET at sacrifice for the identification of metastases to other organs. As noted in Task 2, the MicroPET scanner at UTHSCSA is broken and we were unable to perform this analysis.

f. At sacrifice, tissues from each mouse was harvested for histological preparation. Quantitative bone histomorphometry was performed on sections of long bones to determine the effects of HA on bone metastases.

**Outcomes:** Our initial result suggested that *in vivo* systemic treatment with HMC to treat established bone metastases may help reduce the progression of the bone metastases and thus HMC may be a viable treatment option for patients with already established bone metastases. However, our work also indicates that HMC delivered via oral gavage is not well-tolerated by the animals, particularly once their health is compromised.

While we did not observe a reduction in trabecular bone volume as see in mice under the preventative scenario, we also saw no effect on metastasis in mice. The bulk of the mice were so compromised by extensive disease in the skeleton and throughout the body that HMC treatment had no effect on metastases or survival. This could be due to one of two explanations. First, there is the possibility that HMC is not effective against prostate cancer cells outside of the primary site. While this is plausible, it seems unlikely given the profound effect on prostate cancer cells in vitro and in subcutaneous growth assays. Second, this and the lack of effect on prevention of metastases may be due to poor oral bioavailability of HMC, and difficulty getting to the site of bone metastases. Many conventional chemotherapeutics are ineffective against bone metastases, in part because of difficulty in reaching tumor in the bone metastatic site. To overcome this potential issue, we have begun to explore options that would allow for targeting of HMC to the bone metastatic microenvironment.
KEY RESEARCH ACCOMPLISHMENTS:

- Levels of HAS1, HAS2 and HAS3 expression in prostate cancer cell lines has been determined. HAS1 expression is virtually undetectable in all of the cell lines. HAS2 expression is upregulated in PC-3, DuCaP, VCaP cell lines. HAS3 expression levels are substantially lower than HAS2 in all of the cell lines. HAS3 is expressed most abundantly in PC-3, 22RV1 and DU145 cells. This indicates that HAS2 is likely to be responsible for the bulk of HA production in prostate cancer cells.

- Levels of HA production by prostate cancer cells has been established and has been shown to correlate with tumorigenicity and metastatic behavior. Cell lines that have a more aggressive phenotype in mouse models, such as PC-3, VCaP and DU-145, produce more HA than other prostate cancer cell lines which are less aggressive. These three cell lines are also those initially isolated from the more aggressive cancers (metastatic to bone, bone and brain, respectively).

- Treatment with HMC in vitro has been demonstrated to decrease HAS 2 and HAS3 expression levels in prostate cancer cell lines. The exception to this is DU145, where expression increased slightly in both cases following treatment with HMC. These results have been verified and we are currently working to discover what is unique about DU145.

- Treatment with HMC in vitro has been shown to decrease HA production as measured by ELISA in all of the prostate cancer cell lines that produced detectable levels of HA. Levels of HA in DU145 were reduced but the result was not significant. This has now been verified.

- Treatment with HMC in vitro resulted in a significant reduction in cell growth over time in the entire cell lines examined. This is consistent with anti-tumorigenic behavior. Interestingly, HMC significantly reduced the in vitro growth of DU145 cells despite our findings that it increased expression of HAS2 and HAS3.

- The 3g/kg dose of HMC was well-tolerated by mice and had no observed side effects. However, we have found that with the acidic form of HMC is difficult to get into solution. As a result, we have begun to use the HMC salt solution at a 1mg/kg/day dose.

- All of our data has been repeated with the HMC salt solution and it indeed is as effective in vitro as the acidic form of HMC.
Bioavailability of the acidic form of HMC has been an issue. We have repeated all of Task 1 with the HMC salt solution and found that it does indeed act similarly in vitro.

In vivo evaluation of the HMC salt solution on the growth of prostate cancer cells in vivo has been completed. HMC has significant effects on the growth of both PC-3 and VCaP tumors, and thus may be an excellent treatment for prostate cancer.

In vivo evaluation of HMC for the prevention and treatment of metastases, particularly bone metastases has been completed. Initially experiments indicated that HMC might be effective in the prevention of bone metastases in tumors that have an upregulated HA pathway. However, at the conclusion of the experiment, HMC had little, if any effect on the prevention of bone metastases or on the treatment of existing bone metastases. We are working to repeat these experiments with targeted HMC before we rule out its efficacy completely.

August 2012 Manuscript in Preparation

CONCLUSIONS:

Hyaluronic acid (HA) levels and HAS2 and HAS3 expression levels are elevated in prostate cancer cell lines that are more aggressive in in vivo models of tumor growth and metastasis. Our data indicates that HMC is capable of decreasing HA levels and HAS2 and HAS3 expression in vitro. Furthermore, HMC significantly decreases the growth of prostate cancer cells in vitro, indicating that it may represent a viable option for prostate cancer patients. In vivo testing indicates that there are no serious side effects in mouse models. In vivo analysis of the effects of HMC on tumor growth indicates that it may be a viable treatment in at least a subset of patients with elevated HA levels. All of our data to this point has been repeated with the HMC salt solution and it appears
to be a valid alternative to the acidic form of HMC. We have also eliminated DuCaP cells from in vivo analysis because of difficulty with the cells forming tumors in mice. Unfortunately, the MicroPET scanner we had planned to use is broken and it is unclear when it will be repaired. As a result, we were unable to complete those imaging studies. Our experiments were also hampered some by the retirement of Mr. Barry Grubbs, the senior research technician on the project, following some health issues. We have completed evaluation of HMC for the ability to prevent/treat metastases particularly to bone in the PC-3 prostate cancer model. Despite our hope, HMC does not appear to be an easy treatment to either prevent or treat prostate cancer bone metastases. However, we believe some of the problem may be due to the side effect of systemic treatment with HMC along with poor oral bioavailability to have substantial effects on widely disseminated tumors. We are working with collaborators to see if we can target HMC specifically to metastatic lesions.

Introduction

Prostate cancer is the most common non-cutaneous malignancy in American men. Despite advances in the early diagnosis and treatment of prostate cancer, many patients eventually relapse with advanced prostate cancer. Many of these patients will develop skeletal metastases, a debilitating and devastating complication. Unfortunately, treatment options for patients with advance disease, especially those with bone metastases are limited. Thus, there is an urgent need for therapeutics aimed at preventing and treating advanced prostate cancer.

Both hyaluronic synthase (HAS) and hyaluronic acid (HA) are upregulated in metastatic prostate cancer cells. 7-Acetoxy-4-Methyl Coumarin (HMC) is an inhibitor of hyaluronic synthase. It is commonly available in herbal supplements and, up to now, has been utilized mainly for digestion complaints. We propose that it may be efficacious in the prevention and treatment of prostate cancer. Our hypothesis is that HA is utilized by prostate cancer cells to facilitate growth and metastasis. Thus, reducing the production of HA should reduce the growth and metastatic potential of prostate cancer cells making HA an ideal target for preventing and treating metastatic disease. We set out to determine whether HAS expression and HA production in prostate cancer cells correlates with increased growth both in vitro and in vivo using both real-time PCR and protein expression assays. We also examined whether modulation of HAS expression by HMC inhibited tumor cell growth in vitro and in vivo.

Materials and Methods

Quantitative Expression Analysis. Levels of HAS1, HAS2 and HAS3 expression in prostate cancer cell lines were assayed by Taqman Gene Expression primer and probe sets for each (Applied Biosystems, Foster City, CA).

Quantification of HA synthesis. HA synthesis was quantitated in both cell culture supernatants and in serum collected from mice using a competitive binding assay specific for HA per manufacturer’s instructions (Biotech Trading Partners, Encinitas, CA).

Doubling Time Analysis. Cells were plated at 1x10^6 cells/ml in 24 well plates at 1ml/well containing media without selective agents. Three wells will be harvested and counted with a hemacytometer daily for 4-5 days.

In vivo tumorigenicity (subcutaneous growth). 5x10^6 cells in a 100µl volume were inoculated into 5 to 7 week old male athymic nude mice. Tumor volumes were monitored every other day using caliper measurements.

Results

Figure 1. Quantitative Analysis of HAS3 Expression levels in Harlequin PC3. HAS3 expression is reported relative to expression in the parental untreated PC3 cell line. Note that in all of the prostate cancer cell lines that produce HA, HAS3 expression levels are higher than in the parental untreated PC3 cell line. An increase in HAS2 expression levels is observed in the parental untreated PC3 cell line, however, HMC had no effect on HAS2 expression levels in all of the cell lines except DU145.

Figure 2. HAS synthesis by prostate cancer cell lines. Note that the prostate cancer cell line lines, PC3, VCP and DU145 inhibit HA synthesis. The prostate cancer cell lines, PC3, VCP and DU145 produce detectable levels of HA. HAS3 expression levels in prostate cancer cell lines, PC3, VCP and DU145. The levels of HA synthesis are similar in both the untreated and HMC treated cell lines. HAS3 expression levels in the untreated cell lines were significantly reduced by HMC.

Figure 3. HA synthesis by prostate cancer cell lines. Note that the prostate cancer cell line lines, PC3, VCP and DU145 inhibit HA synthesis. The prostate cancer cell lines, PC3, VCP and DU145 produce detectable levels of HA. HAS3 expression levels in prostate cancer cell lines, PC3, VCP and DU145. The levels of HA synthesis are similar in both the untreated and HMC treated cell lines. HAS3 expression levels in the untreated cell lines were significantly reduced by HMC.

Figure 4. HA synthesis by prostate cancer cell lines. Note that the prostate cancer cell line lines, PC3, VCP and DU145 inhibit HA synthesis. The prostate cancer cell lines, PC3, VCP and DU145 produce detectable levels of HA. HAS3 expression levels in prostate cancer cell lines, PC3, VCP and DU145. The levels of HA synthesis are similar in both the untreated and HMC treated cell lines. HAS3 expression levels in the untreated cell lines were significantly reduced by HMC.

Figure 5. HA synthesis by prostate cancer cell lines. Note that the prostate cancer cell line lines, PC3, VCP and DU145 inhibit HA synthesis. The prostate cancer cell lines, PC3, VCP and DU145 produce detectable levels of HA. HAS3 expression levels in prostate cancer cell lines, PC3, VCP and DU145. The levels of HA synthesis are similar in both the untreated and HMC treated cell lines. HAS3 expression levels in the untreated cell lines were significantly reduced by HMC.

Conclusions

- HAS2 expression levels and HA production
  - ↑ in PC3, VCP and DU145 prostate cancer cell lines.
  - correlate with in vivo tumorigenicity and metastatic potential.

- Cells with a more aggressive in vivo phenotype, express more HAS2 and produce more HA.

- HMC:
  - ↓ in vitro HAS2 and HAS3 expression levels in prostate cancer cell lines.
  - ↓ in vitro production of HA in all of the cell lines that produced detectable levels of HA.
  - ↓ in vivo growth over time in all of the cell lines examined.
  - ↓ growth of PC-3 and VCP prostate cancer tumors

Modulation of HA may be a viable option for augmenting the current standard of care in prostate cancer patients.
“Hyaluronic Acid as a Therapeutic Target for Prostate Cancer”

BACKGROUND AND OBJECTIVES: Both hyaluronan synthase (HAS) and hyaluronic acid (HA) are upregulated in metastatic prostate cancer. 7-Hydroxy-4-Methyl Coumarin (HMC) is an inhibitor of HAS. It is commonly available in herbal supplements and, up to now, has been utilized mainly in Europe for digestive complaints. We hypothesize that HA is utilized by prostate cancer to facilitate growth and metastasis and that it may be efficacious in the prevention and treatment of prostate cancer.

BRIEF DESCRIPTION OF METHODOLOGIES: We set out to determine whether HAS expression and HA production in prostate cancer cells correlates with increased growth both in vitro and in vivo using both real-time PCR and protein expression assays. We also examined whether modulation of HAS expression by HMC inhibited tumor cell growth in vitro and in vivo.

RESULTS TO DATE: HA production was shown to directly correlate with in vivo metastatic potential in seven prostate cancer cell lines. However, of the three HAS enzymes, only expression of HAS2 correlated with the metastatic potential of the cell lines. In vitro, HA levels can be modulated using HMC and tumor cell growth is reduced by HMC treatment in every cell line examined regardless of the level of HA produced. In vivo tumor growth has also been reduced by HMC treatment but only with PC-3 and VCaP prostate cancer cell lines.

CONCLUSIONS: These results indicate that HMC may be a viable treatment option for patients with HA-producing prostate cancer. Additional studies are underway to investigate HMC affects on prostate cancer bone metastases.

IMPACT:
Hyaluronic Acid as a Therapeutic Target in Prostate Cancer

Introduction
Prostate cancer is the most common non-cutaneous malignancy in American men. Despite advances in the early diagnosis and treatment of prostate cancer, many patients eventually relapse with advanced prostate cancer. Many of these patients will develop skeletal metastases, a debilitating and devastating complication. Unfortunately, treatment options for patients with advanced disease, especially those with bone metastases are limited. Thus, there is an urgent need for therapeutics aimed at preventing and treating advanced prostate cancer.

Both hyaluronan synthase (HAS) and hyaluronic acid (HA) are upregulated in metastatic prostate cancer cells. 7-Hydroxy-4-Methyl Coumarin (HMC) is an inhibitor of hyaluronan synthase. It is commonly available in herbal supplements and, up to now, has been utilized mainly for digestion complaints. We propose that it may be efficacious in the prevention and treatment of prostate cancer. Our hypothesis is that HA is utilized by prostate cancer cells to facilitate growth and metastasis. Thus, reducing the production of HA should reduce the growth and metastatic potential of prostate cancer cells making HA an ideal target for preventing and treating metastatic disease. We set out to determine whether HAS and HA production in prostate cancer cells correlates with increased growth both in vitro and in vivo using both real-time PCR and protein expression assays. We also examined whether modulation of HAS expression by HMC inhibited tumor cell growth in vitro and in vivo.

Materials and Methods

Quantitative Expression Analysis. Levels of HAS1, HAS2 and HAS3 expression in prostate cancer cell lines were assayed by Taqman Gene Expression primer and probe sets for each (Applied Biosystems, Foster City, CA).

Quantitation of HA synthesis. HA synthesis was quantitated in both cell culture supernatants and in serum collected from mice using a competitive binding assay specific for HA per manufacturer’s instructions (Biotech Trading Partners, Encinitas, CA).

Doubling Time Analysis. Cells were plated at 1X10^5 cells/ml in 24 well plates at 1ml/well containing media without selective agents. Three wells will be harvested and counted with a hemocytometer daily for 4-5 days.

In vivo tumorigenicity (subcutaneous growth). 5X10^4 cells in a 100µl volume were inoculated into 5 to 7 week old male athymic nude mice. Tumor volumes were monitored every other day using caliper measurements.

Results

Figure 1. Quantitative Analysis of HAS Expression levels by Real-Time PCR. HAS expression is reported relative to expression in the DU145 prostate epithelial cell line. Note that all of the prostate cancer cell lines except for DU145 upregulates HAS expression at higher levels than prostate epithelial cell lines. RWPE-1 and PC3/PC2. DuCaP induced DACaP cells are shown with a bar chart. Of DuCaP only the isolated DuCaP cells.

Figure 2. Quantitative Analysis of HAS Expression levels by Real-Time PCR. HAS expression is reported relative to expression in the DU145 prostate epithelial cell line. Note that all of the prostate cancer cell lines except for DU145 upregulates HAS expression at higher levels than prostate epithelial cell lines. RWPE-1 and PC3/PC2. DuCaP induced DACaP cells are shown with a bar chart. Of DuCaP only the isolated DuCaP cells.

Figure 3. HA synthesis by prostate cancer cell lines. Note that the metastatic prostate cancer cell lines, PC3, VCaP and DU145 make HA. PC3 cells make significantly more HA than other prostate cancer cell lines and the prostate epithelial cell lines, RWPE-1 and RWPE-2. The prostate cancer cell lines make very low levels or undetectable levels of HA. These results correlate with in vitro and in vivo tumorigenicity.

Figure 4. Quantitative Analysis of HAS Expression levels by Real-Time PCR. HAS expression is reported relative to expression in the vehicle treated RWPE-1 prostate epithelial cell line. HAS expression in all of the cell lines except DU145 was significantly reduced by the HA antagonist DPCap.

Figure 5. Quantitative Analysis of HAS Expression levels by Real-Time PCR. HAS expression is reported relative to expression in the vehicle treated RWPE-1 prostate epithelial cell line. HAS expression was significantly reduced in both PC3 and DuCaP but not in DU145 cells, consistent with the results of HAS and HA synthesis analysis (Figures 1 and 3). The other prostate cancer cell lines make very low levels or undetectable levels of HA by this assay and thus were not included here.

Figure 6. HMC effects on tumor volumes and tumor wet weight. A) In vivo growth curves of PC3 tumors treated with control or HMC. Note HMC alone the growth of tumor. B) In vivo growth curves of VCaP tumors treated with control or HMC. Again note that HMC alone the growth of tumor. C) In vivo growth curves of DU145 tumors treated with control (HMC) or HMC. DU145 tumors treated with control (HMC) or HMC grew significantly faster than VCaP or PC3 tumors treated with control or HMC. D) VCaP tumor weight at euthanasia following in vivo treatment with control or HMC. Note that the VCaP tumors treated with HMC weigh significantly less than the control tumors. E) DU145 tumor weight at euthanasia, consistent with the other experiments, in vivo treatment with control and HMC.

Conclusions

- HAS2 expression levels and HA production
  - ↑ in PC3, DuCaP and VCaP prostate cancer cell lines.
  - correlate with in vivo tumorigenicity and metastatic potential.

Cells with a more aggressive in vivo phenotype, express more HAS2 and produce more HA.

- HMC:
  - ↓ in vitro HAS2 and HAS3 expression levels in prostate cancer cell lines.
  - ↓ in vitro production of HA in all of the cell lines that produced detectable levels of HA.
  - ↓ in vitro growth over time in all of the cell lines examined.
  - ↓ growth of PC3 and VCaP prostate cancer tumors

Modulation of HA may be a viable option for augmenting the current standard of care in prostate cancer patients.
